A rigid body is in equilibrium if the sum of all forces acting on it gives a resultant force  $\sum \mathbf{F} = 0$  and couple  $\sum \mathbf{M} = 0$  both equal to zero. Notice that in that case, the resultant couple will be zero with respect to any point, because moving the resultant force  $\sum \mathbf{F} = 0$  to any other point does not introduce any additional moment.

RIGID BODY DYNAMICS The translations of the body require three spatial coordinates. These translations can be taken from any fixed point in the body. Typically the fixed point is the center of mass (CM), denoted as:  $\mathbf{R} =$

*8.09(F14) Chapter 2: Rigid Body Dynamics*

A rigid body consists of a group of particles whose separations are all fixed in magnitude. Six independent coordinates are required to completely specify the position and orientation of a rigid body. For example, the location of the first particle is specified by three coordinates.

Chapter 13: Rotation of a Rigid Body In rigid body dynamics we have two types of motion: translational and rotational, plus a third which is a combination of the two. So far, we have only considered translational motion. This chapter shows us how to include rotation into the dynamics.

If you're looking at the sub-chapters, usually the kinematics chapters precedes the kinetics chapter for the particle case, rigid body case, and the 3D dynamics of the rigid body as well. The ultimate now is that we want to deliver throughout the dynamics causes the kinetics chapter, which is the force and motion relationship.
